

No - you
may not
bathe in
them.

Bath Bombs

Method:

1. Put **20g sodium bicarbonate** and **10g citric acid** into a **beaker** and mix well.
2. Add the **oil**, one drop at a time, mixing well.
3. After a few drops, the mixture should begin to hold together when pressed against the side of the beaker. The mixture should still look quite dry.

Method:

1. Line the second beaker with **cling film**.
2. Pour the mixture into the lined beaker and pack it down tightly.
3. Twist the edges of the cling film together so that the mixture is completely enclosed then pull it out of the beaker.
4. Shape the mixture into a firm ball and very carefully undo the cling film.
5. Leave to dry for 5 minutes.
6. Fill a large bowl with water and drop the bath bomb into it.

How does it work?

- The **sodium bicarbonate** is added to the **citric acid**.
 - Sodium bicarbonate → **base**.
 - Citric acid → **acid** (but that's clear).

There is no water to enable the reaction so you are simply mixing solids.

Why is water needed to facilitate the reaction?

- Without water, **neutralisation** cannot take place.
 - Because there is no medium for the acid and base to dissolve and interact.

How does it work?

- When you add your solid mixture to water the two substances **do react**.
- They **neutralise** each other = acid-base reaction.

Citric
Acid

Baking Soda

Water

Carbon
Dioxide

Sodium Citrate
